PHYSICS
CHAPTER 8 – GRAVITATION

NOTES

➢ **Gravitation or gravitational force:** It is the force of attraction between any two objects having masses. It is an unbalanced force and has acceleration.

➢ **An object moving along a circular path:** When an object moves in a circular path with a certain speed and changes its direction of motion continuously at every point of the path then, the change in direction involves a change in velocity which is called acceleration. This acceleration is towards the center and caused by a force which keeps the body moving along the orbit. This force must be acting towards the center and is called the centripetal force.

➢ **Gravity:** It is the force of attraction between any object and the earth.

➢ **Universal law of gravitation:** The universal law of gravitation states that" every object in the universe attracts every other object with a force which is directly proportional to product of the masses and inversely proportional to the square of the distance between them.

➢ **Mathematical form of the universal law of gravitation:**
According to the universal law of gravitation, the force F between the two objects is directly proportional to the product of the two masses and inversely proportional to the square of the distance between them. That is,

$$F \propto Mm, \tag{8.1}$$

$$F \propto \frac{1}{d^2}, \tag{8.2}$$

Where, M and m are the masses of the two bodies and d is the distance between the centers of the two bodies.

Combining relations (8.1) and (8.2) provides

$$F \propto \frac{Mm}{d^2}. \tag{8.3}$$

or $$F = G\,\frac{Mm}{d^2},$$ (8.4)

where, *G* is called universal gravitation constant or universal constant of gravitation.

- The SI unit of G is **Nm²kg⁻².** The value of G is **6.673×10⁻¹¹ Nm²kg⁻².**

- **Free fall:** The downward journey of an object under the gravitational force (*F*) alone is called free fall. While falling, there is no change in the direction of motion of the object but there will be a change in the magnitude of the velocity.

- **Acceleration due to gravity:** When an object falls towards the earth, an acceleration is involved. This acceleration is called acceleration due to gravity. It is denoted by g. The SI unit of g is ms^{-2}.

- **Mathematical expression for g:**

  The acceleration due to gravity is given by

  or $$g = \frac{GM}{R^2},$$ (8.5)

  where, *G* is the universal gravitation constant

       M is the mass of the earth and

       R is the radius of the earth

- The value of g on the surface of the earth is **9.8 ms⁻².** The value of g is greater at the poles than that at the equator. The value of g decreases on going upward from the surface of the earth.

- **Mass:** The mass of an object is the measure of its inertia. Mass of an object does not change from place to place. i.e., mass remains constant.

- **Weight:** The force with which the earth attracts the body is called the weight of the body on the earth. The weight of a body of mass (*m*). Hence,

  $$W = F = \frac{GMm}{R^2} = mg.$$ (8.6)

- The weight of an object varies with place. The SI unit of weight is **newton (N).**

- Weight of an object on the moon $= \frac{1}{6} \times$**its weight on the earth.**
